

Filesystem Hierarchy Standard

The **Filesystem Hierarchy Standard (FHS)** is maintained by the Linux Foundation to define the directory structure/contents in Linux distributions. The Linux Foundation released Version 3.0 on 3 June 2015 [1]. In the FHS, all files and directories appear under the root directory `/`. FHS is used in all Unix-like operating systems (e.g., Linux distros) [2].

Table 1 - FHS Directory Structure/Description [2].

Directory	Description
<code>/</code>	Root directory of the entire file system hierarchy.
<code>/bin</code>	Essential command binaries (e.g., <code>cat</code> , <code>ls</code> , <code>cp</code>).
<code>/boot</code>	Boot loader files.
<code>/dev</code>	Device files (e.g., <code>/dev/null</code> , <code>/dev/sda1</code> , <code>/dev/tty</code>).
<code>/etc</code>	Host-specific system-wide <i>configuration</i> files.
<code>/home</code> , <code>/root</code>	User home directories, except the root user which is <code>/root</code> .
<code>/lib</code>	Libraries essential for binaries in <code>/bin</code> and <code>/sbin</code>
<code>/media</code>	Mount points for removable media such as DVD-ROMs or flash drives.
<code>/mnt</code>	Temporarily mounted filesystems (may include network locations).
<code>/opt</code>	Optional software packages.
<code>/proc</code>	Virtual filesystem providing process and kernel information as <u>files</u> . In Linux, corresponds to the <code>procfs</code> mount.
<code>/run</code>	Run-time variable data: Information about the running system since last boot (e.g., currently logged-in users and daemons).
<code>/sbin</code>	Essential system binaries (e.g., <code>fsck</code> , <code>init</code> , <code>route</code>).
<code>/sys</code>	Contains information about devices, drivers, and some kernel features.
<code>/tmp</code> , <code>/var/tmp</code>	Temporary files (see also <code>/var/tmp</code>). <code>/tmp</code> is a common location in which all users can store non-critical files. Note: The sticky bit (i.e., <code>drwxrwxrwt</code>) is set on files to prevent users from deleting other user's files.
<code>/usr</code>	Read-only user data (e.g., multi-user utilities and applications).
<code>/usr/bin</code>	Non-essential command binaries that are not needed in single user mode.
<code>/usr/lib</code>	Libraries for the binaries in <code>/usr/bin</code> and <code>/usr/sbin</code> .
<code>/usr/local</code>	Local data specific to this host.
<code>/usr/sbin</code>	Non-essential system binaries.
<code>/var</code>	Variable files expected to change during normal system operation (e.g., logs, spool files, and temporary e-mail files).
<code>/var/log</code>	Log files (e.g., <code>auth.log</code> , <code>syslog</code> , <code>apacah.log</code> , etc.).
<code>/var/mail</code>	Mailbox files (previously located in the deprecated <code>/var/spool/mail</code> directory).
<code>/var/spool</code>	Spool for tasks waiting to be processed (e.g. print queues, outgoing mail queues).

NOTE: This is not an exhaustive FHS description, but is meant to keep the topic high-level and appropriate to the LPI Linux Essentials exam.

We can also conceptualize the FHS graphically. This can be helpful in understanding the "top-level" directories of importance. NOTE: "home" is not included in this graphic

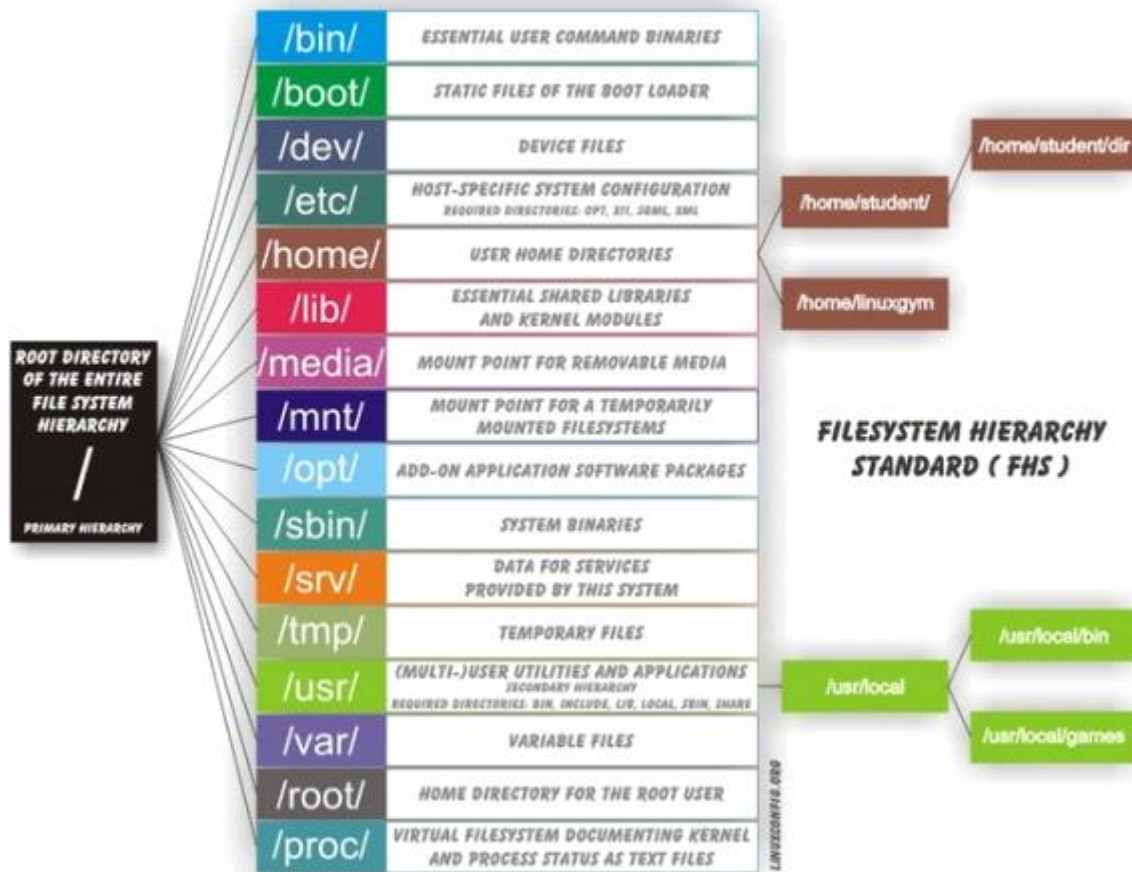

Figure 1 - Filesystem Hierarchy Standard (FHS). L. FHS and L. Aadda, "Linux FHS," 01-Jan-1970. [Online]. Available: <https://sites.google.com/site/linuxaaddaa/linux-fsh>. [Accessed: 10-Jul-2021].

FHS is an important concept for Linux professionals to understand. You will find broad applicability to our C851 learning resource, uCertify Chapter 7: Managing Files, and the LPI Linux Essentials Exam Objectives: 2.1 Command Line Basics, 2.3 Using Directories and Listing Files, 2.4 Creating, Moving and Deleting Files, 4.3 Where Data is Stored, and 5.4 Special Directories and Files [3].
